## 1. INTRODUCTION

Versions 1 to 5 of the ATOVS and AVHRR Processing Package (AAPP) support the processing of direct readout HRPT data from the NOAA polar orbiter satellites. To prepare for the launch of METOP (in 2006), the AAPP navigation modules were revised in AAPP v5. This document details the navigation method that is used in AAPP v5 and subsequent versions of AAPP.

The basic algorithm is the same as in the earlier AAPP versions and has been presented in:
[1] Brunel P. and Marsouin A., 2000, Operational AVHRR navigation results, International Journal of Remote Sensing, Vol. 21, No. 5, 951-972.
[2] Rosborough G.W., Baldwin D. and Emery W., 1994, Precise AVHRR Image Navigation, IEEE Transactions on Geoscience and Remote Sensing, Vol. 32, No. 3, May 1994, 644-657.

The new version differs on the following points:

- several modes of the satellite attitude can be used,
- several scanning geometry are considered (plane, conic, IASI)
- the software is more modular and a new satellite or instrument can be added easily

This text gives a detailed description of the equations used in AAPP version 5 and subsequent versions, and indicates the names of the corresponding AAPP subroutines.

AAPP contains subroutines that are specific to AVHRR navigation:

- invloc and invlorb, to convert the latitude and longitude of the viewed pixel into time and scanning angle,
- estimatt and estimrp, to estimate the attitude error using landmarks true positions and observed viewing vectors.
These routines have not been revisited but only modified concerning the calls to other subroutines. They are not considered here. The navigation subroutines that have not been changed are also ignored in this text.

## 2. DEFINITIONS, UNITS, CONVENTIONS

The equations presented in this document assume the following units: angle in radians, time in seconds and distance in kilometers.

A vector is written $\boldsymbol{V}, \boldsymbol{S M}$ or, if it is a unit vector, $\boldsymbol{v}, \boldsymbol{s} \boldsymbol{m}$. A matrix is written $\mathbf{M}$. The components of a vector $v$ on the X, Y, Z axis of a reference frame are $v(1), v(2), v(3)$, in order to be close to the notations of the FORTRAN code.

In the formula $\boldsymbol{w}=\boldsymbol{u} \times \boldsymbol{v}, \mathrm{x}$ indicates a vector product, which corresponds to :

$$
\begin{aligned}
& w(1)=u(2) \cdot v(3)-u(3) \cdot v(2) \\
& w(2)=u(3) \cdot v(1)-u(1) \cdot v(3) \\
& w(3)=u(1) \cdot v(2)-u(2) \cdot v(1)
\end{aligned}
$$

## Defining a cone

A cone is used for several applications: conical scanning, footprint calculation and IASI viewing geometry. So, a few definitions relative to a cone are given here.

- A cone is defined by an axis and a half angle, $\delta$.
- Using a reference frame where the center is at the cone apex, the X-axis is aligned with the cone axis and Y - and Z -axis are normal to the cone axis, any vector $\boldsymbol{V}$ lying in the cone can be written:

$$
\boldsymbol{V}=\left[\begin{array}{c}
\cos (\delta) \\
\sin (\delta) \cdot \cos (\phi) \\
\sin (\delta) \cdot \sin (\phi)
\end{array}\right]
$$

where $\phi$ is the angle between the plane $(\mathrm{X}, \mathrm{Y})$ and the plane $(\mathrm{X}, \boldsymbol{V})$, varying from 0 to $2 \pi$. This angle has no specific name (unlike the half angle). As it is similar to an azimuth, this name will be used in the document.

Figure 2-1: vector lying in a cone

## Reference frames and conversion matrix

The reference frames used for navigation have a physical meaning and each axis direction can be precisely defined. However, its orientation can be chosen arbitrarily, as long as the reference frame is direct. The orientations already used in AAPP have been kept; they correspond to those of the NOAA documents.

The conversion matrix $\mathbf{M}_{\text {old_to_new }}$ from a reference frame $R_{\text {old }}$ to a reference frame $R_{\text {new }}$ is the matrix that converts the coordinates in $\mathrm{R}_{\text {old }}$ of a vector $\boldsymbol{V}$ into its coordinates in $\mathrm{R}_{\text {new }}$

$$
V_{\text {new }}=\mathbf{M}_{\text {old_to_new }} \times V_{\text {old }}
$$

The $\mathrm{R}_{\text {new }}$ unit vectors in $\mathrm{R}_{\text {old }}$ are the columns of $\mathbf{M}_{\text {new_to_old }}$

$$
\text { the lines of } \mathbf{M}_{\text {old_to_new }}
$$

For all conversion matrices used here: $\quad \mathbf{M}^{-1}=\mathbf{M}^{\mathbf{T}}$

If $\mathrm{R}_{\text {new }}$ is obtained from $\mathrm{R}_{\text {old }}$ by a rotation of angle $\varphi$ about one axis of $\mathrm{R}_{\text {old }}$, the conversion matrices between $\mathrm{R}_{\text {new }}$ and $\mathrm{R}_{\text {old }}$ are given by two of the six formulas:
rotation about X axis rotation about Y axis rotation about Z -axis
$\mathbf{M}_{\text {new_to_old }}:\left[\begin{array}{ccc}1 & 0 & 0 \\ 0 & \cos (\varphi) & -\sin (\varphi) \\ 0 & \sin (\varphi) & \cos (\varphi)\end{array}\right]\left[\begin{array}{ccc}\cos (\varphi) & 0 & \sin (\varphi) \\ 0 & 1 & 0 \\ -\sin (\varphi) & 0 & \cos (\varphi)\end{array}\right]\left[\begin{array}{ccc}\cos (\varphi) & -\sin (\varphi) & 0 \\ \sin (\varphi) & \cos (\varphi) & 0 \\ 0 & 0 & 1\end{array}\right]$
$\mathbf{M}_{\text {old_to_new }}:\left[\begin{array}{ccc}1 & 0 & 0 \\ 0 & \cos (\varphi) & \sin (\varphi) \\ 0 & -\sin (\varphi) & \cos (\varphi)\end{array}\right]\left[\begin{array}{ccc}\cos (\varphi) & 0 & -\sin (\varphi) \\ 0 & 1 & 0 \\ \sin (\varphi) & 0 & \cos (\varphi)\end{array}\right]\left[\begin{array}{ccc}\cos (\varphi) & \sin (\varphi) & 0 \\ -\sin (\varphi) & \cos (\varphi) & 0 \\ 0 & 0 & 1\end{array}\right]$

## 3. REFERENCE FRAMES AND CONVERSION MATRIX

### 3.1. GREENWICH REFERENCE FRAME ( $\mathbf{R}_{\underline{G}}$ )

$\mathrm{R}_{\mathrm{G}}$ is an Earth fixed reference frame.

- The center is at the Earth's gravity center, O.
- $\quad \mathrm{X}_{\mathrm{G}}$ is the line from the Earth's gravity center to the intersection between the equator and the Greenwich meridian, which defines the positive direction.
- $\mathrm{Z}_{\mathrm{G}}$ is the polar axis, positive toward the North Pole.
- $\mathrm{Y}_{\mathrm{G}}$ is normal to $\mathrm{X}_{\mathrm{G}}$ and $\mathrm{Z}_{\mathrm{G}}$ (in the equatorial plane, toward longitude 90 E ).

The following relations are useful:

$$
\begin{array}{ll}
\boldsymbol{O M}=R \cdot\left[\begin{array}{c}
\cos \left(l a_{C}\right) \cdot \cos (l o) \\
\cos \left(l a_{C}\right) \cdot \sin (l o) \\
\sin \left(l a_{C}\right)
\end{array}\right] & \tan \left(l a_{C}\right)=\tan \left(l a_{G}\right) \cdot \frac{R_{P}^{2}}{R_{E}^{2}} \\
R=\frac{R_{P}}{\sqrt{1-e^{2} \cdot \cos ^{2}\left(l a_{C}\right)}} & e^{2}=1-\frac{R_{P}^{2}}{R_{E}^{2}}
\end{array}
$$

with
M : a point on the Earth's surface
lo : longitude of M , i.e. angle from the plane (polar axis, Greenwich meridian) to the plane (polar axis, meridian of M )
$l a_{G} \quad$ : geographical latitude of M , i.e. angle from the equatorial plane to the normal to the Earth ellipsoid
$l a_{C} \quad:$ geocentric latitude of M , i.e. angle from the equatorial plane to OM
$R \quad$ : Earth's radius at M
$R_{E}, R_{P}$ : Earth's equatorial and polar radius; AAPP uses the reference ellipsoid

$$
\text { GRS 80: } \quad R_{E}=6378.137 \mathrm{~km} \quad \text { flattening factor } \mathrm{f}=1 / 298.25722
$$

$$
\Rightarrow \quad R_{P}=(1-\mathrm{f}) R_{E}=6356.752 \mathrm{~km}
$$

### 3.2. LOCAL REFERENCE FRAME OF AN OBSERVATION POINT ( $\mathbf{R}_{\mathrm{L}}$ )

$\mathrm{R}_{\mathrm{L}}$ is an Earth fixed reference frame.

- The center is at the observation point M.
- $\quad \mathrm{Z}_{\mathrm{L}}$ is the local vertical (i.e. the normal to the Earth ellipsoid), positive upward
- $\quad \mathrm{X}_{\mathrm{L}}$ is normal to $\mathrm{Z}_{\mathrm{L}}$ and in the half plane that contains the meridian of the point, positive toward south.
- $\quad \mathrm{Y}_{\mathrm{L}}$ is normal to $\mathrm{X}_{\mathrm{L}}$ and $\mathrm{Z}_{\mathrm{L}}$.
$\mathrm{R}_{\mathrm{L}}$ is deduced from $\mathrm{R}_{\mathrm{G}}$ by two rotations
- rotation of an angle lo about the axis $\mathrm{Z}_{\mathrm{G}}$, which gives an intermediate reference frame
- rotation of an angle $\pi / 2-l a_{G}$ about the Y -axis of the intermediate reference frame

So, the conversion matrix $L$ from $R_{G}$ to $R_{L}$ is:

$$
\begin{aligned}
& \mathbf{L}=\left[\begin{array}{ccc}
\cos \left(\pi / 2-l a_{G}\right) & 0 & -\sin \left(\pi / 2-l a_{G}\right) \\
0 & 1 & 0 \\
\sin \left(\pi / 2-l a_{G}\right) & 0 & \cos \left(\pi / 2-l a_{G}\right)
\end{array}\right] \times\left[\begin{array}{ccc}
\cos (l o) & \sin (l o) & 0 \\
-\sin (l o) & \cos (l 0) & 0 \\
0 & 0 & 1
\end{array}\right] \\
& \mathbf{L}=\left[\begin{array}{ccc}
\sin \left(l a_{G}\right) & 0 & -\cos \left(l a_{G}\right) \\
0 & 1 & 0 \\
\cos \left(l a_{G}\right) & 0 & \sin \left(l a_{G}\right)
\end{array}\right] \times\left[\begin{array}{ccc}
\cos (l o) & \sin (l o) & 0 \\
-\sin (l o) & \cos (l 0) & 0 \\
0 & 0 & 1
\end{array}\right] \\
& \mathbf{L}=\left[\begin{array}{ccc}
\sin \left(l a_{G}\right) \cdot \cos (l o) & \sin \left(l a_{G}\right) \cdot \sin (l o) & -\cos \left(l a_{G}\right) \\
-\sin (l o) & \cos (l o) & 0 \\
\cos \left(l a_{G}\right) \cdot \cos (l o) & \cos \left(l a_{G}\right) \cdot \sin (l o) & \sin \left(l a_{G}\right)
\end{array}\right]
\end{aligned}
$$

$R_{L}$ is used only to calculate the viewing angle of an object, sun or satellite, $S$, seen from an observation point on Earth, M:

- the zenith angle, $\theta$, which is the angle between the local vertical and the point-to-object vector, varies from 0 to 180 degrees.
- the azimuth angle, $A z$, which is the angle between a vertical half plane containing the north direction (i.e. opposite to $X_{L}$ ) and the point-to-object vector (see Figure 3-2); this angle varies from -180 to 180 degrees, is 0 at true north and positive toward east.
The azimuth angle definition is the one of the NOAA level $\mathbf{1 b}$.
Due to $\mathrm{R}_{\mathrm{L}}$ axis orientation, $A z$ is the angle from the point-to-object vector to the vertical half plane containing the north direction.

The vector $\boldsymbol{M S}$ can be expressed in $\mathrm{R}_{\mathrm{L}}$ :

$$
\boldsymbol{M S}=D\left[\begin{array}{c}
\sin (\theta) \cdot \cos (\pi-A z) \\
\sin (\theta) \cdot \sin (\pi-A z) \\
\cos (\theta)
\end{array}\right]=D\left[\begin{array}{c}
\sin (\theta) \cdot \cos (A z) \\
-\sin (\theta) \cdot \sin (A z) \\
\cos (\theta)
\end{array}\right]
$$

where $D$ is the distance from the observation point to the object.

| NWP SAF | AAPP DOCUMENTATION <br> AAPP Navigation | Doc ID : NWPSAF-MF-UD- <br> Oos- Navigation.doc <br> Version: 1.3 <br> Date : October 2011 |
| :---: | :---: | :--- |

The conversion matrix $\mathbf{L}$ is calculated in two subroutines: zenazi, the general routine to calculate the viewing angles and initrack, which is adapted to the case of a tracking station.

### 3.3. NOMINAL ATTITUDE REFERENCE FRAME ( $\mathbf{R}_{A}$ )

$\mathrm{R}_{\mathrm{A}}$ represents to the nominal orientation of the spacecraft, i.e. the attitude that the spacecraft would have if the attitude control system was perfect. The precise definition of this frame depends on the current attitude mode, "local normal pointing" for NOAA POES and "yaw steering" for METOP. However, the various attitude modes of the polar orbiter satellites are not so different and a general definition can be given for $\mathrm{R}_{\mathrm{A}}$ :

- The center is at the satellite gravity center.
- $X_{A}$ is close to the local terrestrial vertical, positive toward the Earth.
- $\mathrm{Y}_{\mathrm{A}}$ is nearly collinear to the satellite velocity, opposite in direction.
- $\mathrm{Z}_{\mathrm{A}}$ is nearly orthogonal to the orbit plane, positive in the direction of the angular momentum vector of the orbit i.e toward the left of the trajectory.

The following sections precisely define $\mathrm{R}_{\mathrm{A}}$ and calculate the conversion matrix $\mathbf{T}$ from $\mathrm{R}_{\mathrm{A}}$ to $\mathrm{R}_{\mathrm{G}}$, for several attitude modes. The matrix $\mathbf{T}$ is obtained by calculating $\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{w}$, the unit vectors of $\mathrm{R}_{\mathrm{A}}$ in $\mathrm{R}_{\mathrm{G}}$.

$$
\mathbf{T}=\left[\begin{array}{lll}
u(1) & v(1) & w(1) \\
u(2) & v(2) & w(2) \\
u(3) & v(3) & w(3)
\end{array}\right]
$$

Figure 3-3: $\mathbf{R}_{\mathrm{A}}$ reference frame

### 3.3.1. Local normal pointing mode ( $\mathbf{R}_{\mathrm{A} 0}$ )

$\mathrm{R}_{\mathrm{A} 0}$ is defined as follows:

- $\quad \mathrm{X}_{\mathrm{A} 0}$ is aligned with the local terrestrial vertical (i.e. the normal to the Earth ellipsoid passing by the satellite), positive toward the Earth.
- $\mathrm{Z}_{\mathrm{A} 0}$ is normal to $\mathrm{X}_{\mathrm{A} 0}$ and to the satellite velocity; it is positive in the direction of the angular momentum vector of the orbit.
- $\mathrm{Y}_{\mathrm{A} 0}$ completes the orthogonal system

The vector $\boldsymbol{u}$ is calculated with the satellite longitude, lon, and geographical latitude $l a t_{G}$

$$
\boldsymbol{u}=\left[\begin{array}{c}
-\cos \left(\text { lat }_{G}\right) \cdot \cos (\text { lon } \\
-\cos \left(\text { lat }_{G}\right) \cdot \sin (\text { lon } \\
-\sin \left(\text { lat }_{G}\right)
\end{array}\right]
$$

The vector $\boldsymbol{w}$ is normal to $\boldsymbol{u}$ and to the satellite velocity vector $\boldsymbol{V}$. This vector is the "absolute" velocity or the velocity in an inertial reference frame (as usual orbit prediction).

$$
\begin{array}{ll} 
& w=-\boldsymbol{u} \times \boldsymbol{V} /\|\boldsymbol{u} \times V\| \\
\text { And finally: } & \boldsymbol{v}=\boldsymbol{w} \times \boldsymbol{u}
\end{array}
$$

| NWP SAF | AAPP DOCUMENTATION <br> AAPP Navigation | Doc ID : NWPSAF-MF-UD- <br> Oos- Navigation.doc <br> Version: 1.3 <br> Date : October 2011 |
| :---: | :---: | :--- |

### 3.3.2. Yaw steering mode ( $\mathbf{R}_{\mathrm{A} 1}$ )

$\mathrm{R}_{\mathrm{A} 0}$ and $\mathrm{R}_{\mathrm{A} 1}$ have the same X -axis and they differ on the Y - and Z -axis:

- $\mathrm{X}_{\mathrm{Al}}$ is aligned with the local terrestrial vertical (i.e. the normal to the Earth ellipsoid passing by the satellite), positive toward the Earth.
- $\mathrm{Z}_{\mathrm{A} 1}$ is normal to $\mathrm{X}_{\mathrm{A} 1}$ and to the satellite velocity relative to the Earth, i.e. the velocity in $\mathrm{R}_{\mathrm{G}}$; it is positive in the direction of the angular momentum vector of the orbit.
- $\mathrm{Y}_{\mathrm{Al}}$ completes the orthogonal system

The calculations are the same as in 3.3.1 except for the vector $\boldsymbol{w}$ is normal to $\boldsymbol{u}$ and to the satellite velocity vector, $V \boldsymbol{r}$, in the reference frame $\mathrm{R}_{\mathrm{G}}$.

$$
\boldsymbol{w}=-\boldsymbol{u} \times V r /\|u \times V r\|
$$

$V \boldsymbol{r}$ is a relative velocity vector, obtained as follows:

$$
\begin{aligned}
\boldsymbol{V}=\boldsymbol{V}-\boldsymbol{\sigma}_{\boldsymbol{E}} \times \boldsymbol{O} \boldsymbol{S} \quad \Leftrightarrow \quad & V r_{R_{G}}(1)=V_{R_{G}}(1)+\omega_{E} \cdot \operatorname{OS}(2)_{R_{G}} \\
& V r_{R_{G}}(2)=V_{R_{G}}(2)-\omega_{E} \cdot O S(1)_{R_{G}} \\
& V r_{R_{G}}(3)=V_{R_{G}}(3)
\end{aligned}
$$

with $\boldsymbol{\sigma}_{E} \quad$ : angular velocity vector of the Earth

$$
\varpi_{E}=7.29211514710^{-5} \mathrm{rad} / \mathrm{s} \quad \text { (i.e. } 6.300387487 \mathrm{rad} / \text { day ) }
$$

OS : vector from Earth's gravity centre to satellite

### 3.3.3. Geocentric mode ( $\mathbf{R}_{\mathrm{A} 2}$ )

$\mathrm{R}_{\mathrm{A} 2}$ is defined as follows:

- $\mathrm{X}_{\mathrm{A} 2}$ is aligned with the line from the Earth center to the satellite center, i.e. the geocentric vertical, positive toward the Earth.
- $Z_{A 2}$ is normal to $X_{A 2}$ and to the satellite velocity, i.e. orthogonal to the orbit plane; it is positive in the direction of the angular momentum vector of the orbit.
- $\mathrm{Y}_{\mathrm{A} 2}$ completes the orthogonal system

The calculations are simpler: $\boldsymbol{u}$ directly depends on the satellite Cartesian coordinates and $\boldsymbol{w}$ is normal to $\boldsymbol{u}$ and to the satellite velocity vector $\boldsymbol{V}$.

$$
\begin{aligned}
& u=-\boldsymbol{O S} /\|O S\| \\
& \boldsymbol{w}=-\boldsymbol{u} \times V /\|u \times V\| \\
& v=\boldsymbol{w} \times \boldsymbol{u}
\end{aligned}
$$

### 3.3.4. Velocity calculations

It should be noted that the velocity vectors stored in the "satpos" files are relative velocity vectors in $\mathrm{R}_{\mathrm{G}}$. They have been calculated by one of the subroutines pvitogrw, pvi50togrw or pvitegrw.

The matrix $\mathbf{T}$ is calculated by the subroutine snagre, which use a "satpos" velocity vector as input. So, snagre does not convert $\boldsymbol{V}$ into $\boldsymbol{V r}$ but $\boldsymbol{V r}$ into $\boldsymbol{V}$, when needed (NOAA operational mode and geocentric mode):

| NWP SAF | AAPP DOCUMENTATION <br> AAPP Navigation | Doc ID : NWPSAF-MF-UD- <br> Oos- Navigation.doc <br> Version: 1.3 <br> Date : October 2011 |
| :---: | :---: | :--- |

$$
\begin{aligned}
& \Leftrightarrow \quad V_{R_{G}}(1)=V r_{R_{G}}(1)-\omega_{E} \cdot O S(2)_{R_{G}} \\
& V_{R_{G}}(2)=V r_{R_{G}}(2)+\omega_{E} \cdot O S(1)_{R_{G}} \\
& V_{R_{G}}(3)=V r_{R_{G}}(3)
\end{aligned}
$$

### 3.4. SPACECRAFT-FIXED REFERENCE FRAME (Rs)

$R_{S}$ is defined as follows:

- The center is at the satellite gravity center.
- $\mathrm{X}_{\mathrm{S}}$ is the "vertical" axis of the spacecraft.
- $\mathrm{Y}_{\mathrm{S}}$ is the "longitudinal" axis of the spacecraft.
- $\mathrm{Z}_{\mathrm{S}}$ is the "transversal" axis of the spacecraft.

These axes are defined precisely with respect to some elements of the spacecraft structure, their positive direction being consistent with the spacecraft nominal orientation.
$\mathrm{R}_{\mathrm{S}}$ should be perfectly aligned with $\mathrm{R}_{\mathrm{A}}$, but it differs from it by three small rotation angles: yaw about $X_{A}$, roll about $Y_{A}$ and pitch about the $Z_{A}$. Using the small angle approximation, the conversion matrix between $R_{S}$ and $R_{A}$ are given by simple formulas.
conversion from $\mathrm{R}_{\mathrm{S}}$ to $\mathrm{R}_{\mathrm{A}}$
$\mathbf{A}=\left[\begin{array}{ccc}1 & p & -r \\ -p & 1 & y \\ r & -y & 1\end{array}\right]$

$$
\text { conversion from } R_{A} \text { to } R_{S}
$$

$$
\mathbf{A}^{\mathbf{T}}=\left[\begin{array}{ccc}
1 & -p & r \\
p & 1 & -y \\
-r & y & 1
\end{array}\right]
$$

where $y, r$, and $p$ are the yaw, roll and pitch angles.

The sign conventions are the following:

$$
\begin{array}{ll}
\text { yaw }>0 & \text { : the spacecraft longitudinal axis is orientated toward the right of the trajectory } \\
\text { roll }>0 & \text { : the spacecraft vertical axis is on the right of the sub-track } \\
\text { pitch }>0 & \text { : the spacecraft vertical axis is behind the sub-point }
\end{array}
$$

The attitude matrix $\mathbf{A}$ is calculated in the subroutine calatt

### 3.5. INSTRUMENT REFERENCE FRAME ( $\mathbf{R}_{I}$ )

Each instrument is mounted on the spacecraft but some misalignments may occur. So, the instrumentfixed reference frame $R_{I}$, which should be perfectly aligned with $R_{S}$, may differ slightly from $R_{S}$ it by three small misalignment angles.
$R_{I}$ is defined as follows:

- The center is at the satellite gravity center.
- $X_{I}$ is nearly aligned with $X_{S}$.
- $\mathrm{Y}_{\mathrm{I}}$ is nearly aligned with $\mathrm{Y}_{\mathrm{s}}$.
- $\mathrm{Z}_{\mathrm{I}}$ is nearly aligned with $\mathrm{Z}_{\mathrm{s}}$.
$R_{I}$ is obtained from $R_{S}$ by 3 rotations: in yaw about $X_{S}$, in roll about $Y_{S}$ and in pitch about $Z_{S}$.

The conversion matrices are the following:
conversion from $\mathrm{R}_{\mathrm{I}}$ to $\mathrm{R}_{\mathrm{S}}$
$\mathbf{D}=\left[\begin{array}{ccc}1 & p_{I} & -r_{I} \\ -p_{I} & 1 & y_{I} \\ r_{I} & -y_{I} & 1\end{array}\right]$
where $y_{I}, r_{I}$ and $p_{I}$ are the misalignment angles in yaw, roll and pitch.

### 3.6. INTERMEDIATE REFERENCE FRAMES

Additional reference frames are used for some instruments. They are defined below.
$R_{1}$, useful for an instrument inclined forward or backward of the satellite nadir, is deduced from $R_{I}$ by a rotation of an angle $\beta$ about the instrument transversal axis $\mathrm{Z}_{\mathrm{I}}$ :

- The center is at the satellite gravity center.
- $\mathrm{X}_{1}$ is obtained from $\mathrm{X}_{\mathrm{I}}$ by a rotation of $\beta$ about $\mathrm{Z}_{\mathrm{I}}$.
- $\mathrm{Y}_{1}$ is obtained from $\mathrm{Y}_{\mathrm{I}}$ by a rotation of $\beta$ about $\mathrm{Z}_{\mathrm{I}}$
- $\mathrm{Z}_{1}=\mathrm{Z}_{\mathrm{I}}$.

The conversion matrix from $R_{1}$ to $R_{I}$ is;

$$
\mathbf{M}_{\mathbf{1}}=\left[\begin{array}{ccc}
\cos (\beta) & -\sin (\beta) & 0 \\
\sin (\beta) & \cos (\beta) & 0 \\
0 & 0 & 1
\end{array}\right]
$$

$\beta$ is counted positively according to the direct orientation of $\mathrm{R}_{\mathrm{I}}$, which means:
$\beta>0 \quad \mathrm{X}_{1}$ looks backwards of the satellite sub-point (same convention as for the roll)
$\mathrm{R}_{2}$, useful to define IASI scanning and to calculate the instrument footprint, has its X-axis aligned with the viewing direction. $R_{2}$ is deduced from $R_{1}$ by a rotation of an angle $-\alpha$ about axis $Y_{1}$ (the negative sign is due to the scanning angle definition, see 4.2 for details):

- The center is at the satellite gravity center.
- $\mathrm{X}_{2}$ is obtained from $\mathrm{Z}_{1}$ by a rotation of $-\alpha$ about $\mathrm{Y}_{1}$.
- $\mathrm{Y}_{2}=\mathrm{Y}_{1}$.
- $\mathrm{Z}_{2}$ is obtained from $\mathrm{Z}_{1}$ by a rotation of $-\alpha$ about $\mathrm{Y}_{1}$

The conversion matrix from $\mathrm{R}_{2}$ to $\mathrm{R}_{1}$ is:

$$
\mathbf{M}_{\mathbf{2}}=\left[\begin{array}{ccc}
\cos (-\alpha) & 0 & \sin (-\alpha) \\
0 & 1 & 0 \\
-\sin (-\alpha) & 0 & \cos (-\alpha)
\end{array}\right]=\left[\begin{array}{ccc}
\cos (\alpha) & 0 & -\sin (\alpha) \\
0 & 1 & 0 \\
\sin (\alpha) & 0 & \cos (\alpha)
\end{array}\right]
$$

$\alpha$ is counted positively according to the direct orientation of $\mathrm{R}_{1}$, which means:
$\infty>0 \quad \mathrm{X}_{2}$ looks on the left of the satellite trajectory

| NWP SAF | AAPP DOCUMENTATION <br> AAPP Navigation | Doc ID : NWPSAF-MF-UD- <br> Oos Navigation.doc <br> Version: 1.3 <br> Date : October 2011 |
| :---: | :---: | :--- |

$\mathrm{R}_{3}$, useful to calculate the instrument footprint in case of conical scanning, has its X -axis aligned with the viewing direction. $R_{3}$ is deduced from $R_{1}$ by two rotations

- rotation of an angle $\phi$ about axis $X_{1}$, which gives the intermediate reference frame $\mathrm{R}_{13}$
- rotation of an angle $\delta$ about axis $\mathrm{Z}_{13}$, which gives the reference frame $\mathrm{R}_{3}$

The conversion matrix from $R_{3}$ to $R_{1}$ is:

$$
\begin{aligned}
& \mathbf{M}_{\mathbf{3}}=\mathbf{M}_{\mathbf{1 3} \_ \text {to_1 }} \times \mathbf{M}_{\mathbf{3} \_ \text {to_13 }}=\left[\begin{array}{ccc}
1 & 0 & 0 \\
0 & \cos (\boldsymbol{\phi}) & -\sin (\boldsymbol{\phi}) \\
0 & \sin (\boldsymbol{\phi}) & \cos (\phi)
\end{array}\right] \times\left[\begin{array}{ccc}
\cos (\boldsymbol{\delta}) & -\sin (\boldsymbol{\delta}) & 0 \\
\sin (\boldsymbol{\delta}) & \cos (\boldsymbol{\delta}) & 0 \\
0 & 0 & 1
\end{array}\right] \\
& \mathbf{M}_{\mathbf{3}}=\left[\begin{array}{ccc}
\cos (\boldsymbol{\delta}) & -\sin (\boldsymbol{\delta}) & 0 \\
\sin (\boldsymbol{\delta}) \cdot \cos (\boldsymbol{\phi}) & \cos (\boldsymbol{\delta}) \cdot \cos (\boldsymbol{\phi}) & -\sin (\boldsymbol{\phi}) \\
\sin (\boldsymbol{\delta}) \cdot \sin (\boldsymbol{\phi}) & \cos (\boldsymbol{\delta}) \cdot \sin (\boldsymbol{\phi}) & \cos (\phi)
\end{array}\right]
\end{aligned}
$$

Figure 3-4: $\mathbf{R}_{\mathbf{I}}, \mathbf{R}_{1}$ and $\mathbf{R}_{2}$ reference frames.
$\mathrm{R}_{\mathrm{I}}$ (in red) is rotated by an angle $\beta$ about the axis $\mathrm{Z}_{\mathrm{I}}$ to obtain $\mathrm{R}_{1}$ (in black), which is rotated by an angle $-\alpha$ about the axis $\mathrm{Y}_{1}$ to obtain $\mathrm{R}_{2}$ (in blue).

## 4. SCANNING GEOMETRY

### 4.1. PRINCIPLES

The viewing direction of the IFOV center (IFOV = Instantaneous Field of View) can be calculated in the spacecraft-fixed reference frame $\mathrm{R}_{\mathrm{S}}$ in three stages:
a) the line and pixel numbers are converted into a time and an angle, scanning angle or scanning azimuth,
b) the time and angle gives the unit vector of the direction satellite-toward-viewed-point (sm) in the reference frame $\mathrm{R}_{\mathrm{I}}$,
c) the unit vector is converted from $R_{I}$ to $R_{S}$, taken into account the instrument misalignments.

Stages a) and b) depend on the scanning geometry and are described in the following paragraphs. Stage c) is considered as independent of the scanning geometry and made as follows:

$$
\begin{aligned}
& \boldsymbol{s} \boldsymbol{m}_{\mathbf{R}_{\mathbf{S}}}=\mathbf{D} \boldsymbol{s} \boldsymbol{m}_{\mathbf{R}_{\mathbf{I}}}=\left[\begin{array}{ccc}
1 & p_{I} & -r_{I} \\
-p_{I} & 1 & y_{I} \\
r_{I} & -y_{I} & 1
\end{array}\right] \boldsymbol{s \boldsymbol { m } _ { \mathbf { R } _ { \mathbf { I } } }} \\
& s m_{R_{S}}(1)=s m_{R_{I}}(1)+p_{I} \cdot s m_{R_{I}}(2)-r_{I} \cdot s m_{R_{I}}(3) \\
& s m_{R_{S}}(2)=-p_{I} \cdot s m_{R_{I}}(1)+s m_{R_{I}}(2)+y_{I} \cdot s m_{R_{I}}(3) \\
& s m_{R_{S}}(3)=r_{I} \cdot s m_{R_{I}}(1)-y_{I} \cdot s m_{R_{I}}(2)+s m_{R_{I}}(3)
\end{aligned}
$$

There is not a unique subroutine associated to each subsection of section 4 .
$\begin{array}{lr}\text { lptoviewvect } & \text { do the calculations presented in 4.2, } 4.3 \text { and } 4.1 \\ \text { lptoviewvect_iasi } & \text { do the calculations presented in } 4.4 \text { and } 4.1\end{array}$
IASI has been considered separately since four pixels are obtained simultaneously, as explained in 4.4.

### 4.2. SCANNING IN A PLANE

Most radiometers scanning in a plane are cross-track scanners, i.e. they scan perpendicular to the direction of movement of the satellite. The scanning plane may also be tilted backward or forward, by an angle $\beta$ as defined in 3.6.

The line and pixel numbers are converted into time and scanning angle as follows:

$$
\begin{aligned}
& t=t_{0}+\left(l-l_{0}\right) \cdot T_{\text {stepL }}+t_{\text {offset }}+(p-1) \cdot T_{\text {step } P} \\
& \alpha=\left(p-p_{0}\right) \cdot \alpha_{\text {step }}
\end{aligned}
$$

with $\quad l, l_{0} \quad:$ line number and reference line number
$t, t_{0} \quad:$ start times of the line numbers 1 and $1_{0}$
$p \quad$ : pixel number
$p_{0} \quad$ : pixel number at sub-track, i.e. (real) pixel number when the viewing direction is aligned with $\mathrm{X}_{1}$
$\alpha \quad$ : scanning angle, defined as the angle from the viewing direction to the axis $\mathrm{Z}_{1}$ counted positively according to the direct orientation of $\mathrm{R}_{1}$

## $\alpha>0 \quad$ on the left of the satellite trajectory

$\alpha_{\text {step }} \quad:$ center to center FOV step angle (FOV = Field of View),
as the angle $\alpha$ increases from right to left

$$
\alpha_{\text {step }}>0 \text { for a radiometer scanning from right to left }
$$

$T_{\text {stepL }}$ : full scan period, i.e. the time interval between two consecutive lines
$T_{\text {step } P} \quad:$ step time / FOV, i.e. the time interval between two consecutive pixels
$t_{\text {offset }}$ : time interval between the start time and the first pixel of the line (initial offset time from TIP to start of integration period, for NOAA)

The above equations and definitions are based on the NOAA satellite scanning instrument parameters. However they are general enough to be applied to other instruments. For NOAA instrument, the time is obtained through the TIP clock (TIP=TIROS Information Processor) onboard the spacecraft.

The viewing direction unit vector, $\boldsymbol{s m}$, is in the scanning plane $\left(\mathrm{Z}_{1}, \mathrm{X}_{1}\right)$ and its angle with the axis $\mathrm{Z}_{1}$ is $\pi / 2-\alpha$.

$$
\boldsymbol{s} \boldsymbol{m}_{\mathbf{R}_{\mathbf{1}}}=\left[\begin{array}{c}
\sin (\pi / 2-\alpha) \\
0 \\
\cos (\pi / 2-\alpha)
\end{array}\right]=\left[\begin{array}{c}
\cos (\alpha) \\
0 \\
\sin (\alpha)
\end{array}\right]
$$

For a cross-track scanner, $\beta=0$, the above formula directly gives viewing vector in $R_{I}$. In the general case, the viewing vector is converted from $\mathrm{R}_{1}$ to $\mathrm{R}_{\mathrm{I}}$ with the matrix $\mathbf{M}_{1}$ defined in 3.6:

$$
\boldsymbol{s} \boldsymbol{m}_{\mathbf{R}_{\mathbf{I}}}=\mathbf{M}_{\mathbf{1}} \boldsymbol{s} \boldsymbol{m}_{\mathbf{R}_{\mathbf{1}}}=\left[\begin{array}{ccc}
\cos (\beta) & -\sin (\beta) & 0 \\
\sin (\beta) & \cos (\beta) & 0 \\
0 & 0 & 1
\end{array}\right] \times\left[\begin{array}{c}
\cos (\alpha) \\
0 \\
\sin (\alpha)
\end{array}\right]=\left[\begin{array}{c}
\cos (\beta) \cdot \cos (\alpha) \\
\sin (\beta) \cdot \cos (\alpha) \\
\sin (\alpha)
\end{array}\right]
$$

| NWP SAF | AAPP DOCUMENTATION <br> AAPP Navigation | Doc ID : NWPSAF-MF-UD- <br> oos_Navigation.doc <br> Version : 1.3. <br> Date : October 2011 |
| :---: | :---: | :--- |

### 4.3. CONICAL SCANNING

The radiometer viewing direction lies in a cone and rotates about the cone axis at a constant speed. The cone axis is in the instrument longitudinal plane, aligned with the vertical axis or inclined forward or backward, by an angle $\beta$ (as defined in 3.6). It corresponds to the axis $\mathrm{X}_{1}$ of $\mathrm{R}_{1}$. A line corresponds to a limited part of the cone, forward or backward of the cone axis.

The line number is converted into time as in 4.2 and the pixel number is converted into scanning azimuth by the following equations:

With the angle $\gamma$ and pixel $\mathrm{p}_{0}$ definitions, $\gamma$ and $\gamma_{\text {step }}$ have the following signs with respect to the satellite trajectory:
if backward scanning $\gamma>0$ on the left $\quad \gamma_{\text {step }}>0$ scanning from right to left if forward scanning $\gamma>0$ on the right $\quad \gamma_{\text {step }}>0$ scanning from left to right

The scanning azimuth and half angle, $\delta$, give the viewing vector in $\mathrm{R}_{1}$ (as presented in 2 ):

$$
\boldsymbol{s m _ { \mathrm { R } _ { 1 } }}=\left[\begin{array}{c}
\cos (\delta) \\
\sin (\delta) \cdot \cos (\phi) \\
\sin (\delta) \cdot \sin (\phi)
\end{array}\right]
$$

If the cone axis is aligned with the instrument vertical, $\beta=0$, the above formula directly gives viewing vector in $\boldsymbol{R}_{I}$. In the general case, the viewing vector is converted from $\mathrm{R}_{1}$ to $\mathrm{R}_{\mathrm{I}}$ with the matrix $\mathbf{M}_{1}$ defined in 3.6:

$$
\begin{gathered}
\boldsymbol{s \boldsymbol { m } _ { \mathbf { R } _ { \mathbf { I } } } = \mathbf { M } _ { \mathbf { 1 } } \boldsymbol { s \boldsymbol { m } _ { \mathbf { R } _ { \mathbf { 1 } } } } = [ \begin{array} { c c c } 
{ \operatorname { c o s } ( \beta ) } & { - \operatorname { s i n } ( \beta ) } & { 0 } \\
{ \operatorname { s i n } ( \beta ) } & { \operatorname { c o s } ( \beta ) } & { 0 } \\
{ 0 } & { 0 } & { 1 }
\end{array} ] \mathrm { X } [ \begin{array} { c } 
{ \operatorname { c o s } ( \delta ) } \\
{ \operatorname { s i n } ( \boldsymbol { \delta } ) \cdot \operatorname { c o s } ( \phi ) } \\
{ \operatorname { s i n } ( \delta ) \cdot \operatorname { s i n } ( \phi ) }
\end{array} ]} \\
\boldsymbol{s \boldsymbol { m } _ { \mathbf { R } _ { \mathbf { I } } }}=\left[\begin{array}{c}
\cos (\beta) \cdot \cos (\delta)-\sin (\beta) \cdot \sin (\delta) \cdot \cos (\phi) \\
\sin (\beta) \cdot \cos (\delta)+\cos (\beta) \cdot \sin (\delta) \cdot \cos (\phi) \\
\sin (\delta) \cdot \sin (\phi)
\end{array}\right]
\end{gathered}
$$

| NWP SAF | AAPP DOCUMENTATION <br> AAPP Navigation | Doc ID : NWPSAF-MF-UD- <br> Oos-Navigation.doc <br> Version: 1.3 <br> Date : October 2011 |
| :---: | :---: | :--- |

### 4.4. IASI SCANNING

IASI instrument, Infrared Atmospheric Sounding Interferometer, is a sounder coupled to an integrated imaging subsystem (IIS). IASI field of view contains 4 sounder pixels and an IIS image of 64 by 64 pixels. The operational IASI navigation will be based on a co-registration of IIS and AVHRR, so the AVHRR Earth location will be converted into an IASI Earth location. Such a method has been adopted because IASI is attached on METOP platform via a vibration damping mechanism.
This section is restricted to IASI sounder and simply applies the geometrical laws of the scanning, producing a "draft" navigation.

IASI scanning can be summarized as follows

- a so-called optical axis moves in a plane normal to the spacecraft longitudinal axis,
- a "view" corresponds to 4 pixels, at a given angular distance, $\zeta$, of the optical axis.

A view is considered as instantaneous. Its line and pixel numbers are converted into time of the view and scanning angle of the optical axis, $\alpha_{\text {opt }}$, with the equations of section 4.2. Then the optical axis unit vector, $\boldsymbol{s} \boldsymbol{o}$, is given in $\mathrm{R}_{\mathrm{I}}$ by:

$$
\boldsymbol{s \boldsymbol { o } _ { \mathbf { R } _ { \mathbf { I } } } = [ \begin{array} { c } 
{ \operatorname { c o s } ( \alpha _ { o p t } ) } \\
{ 0 } \\
{ \operatorname { s i n } ( \alpha _ { \text { opt } } ) }
\end{array} ] , ~ ]}
$$

The four pixels lie in a cone. The cone axis is the optical axis, so, and the half angle is the small angle $\xi$. so is aligned with $X_{2}$ axis. So, the viewing direction of each pixel $M_{i}$ is obtained in $R_{2}$ by:

$$
\boldsymbol{s m}_{\boldsymbol{i}_{\mathbf{R}_{\mathbf{2}}}}=\left[\begin{array}{c}
\cos (\zeta) \\
\sin (\zeta) \cdot \cos \left(\phi_{i}\right) \\
\sin (\zeta) \cdot \sin \left(\phi_{i}\right)
\end{array}\right]=\left[\begin{array}{c}
1 \\
\zeta \cdot \cos \left(\phi_{i}\right) \\
\zeta \cdot \sin \left(\phi_{i}\right)
\end{array}\right]
$$

The "IASI scan azimuth" values are dictated by the direct orientation of $\mathrm{R}_{2}$ and the numbering of the IASI pixels:

$$
\begin{array}{ll}
\phi_{1}=7 \pi / 4 & \mathrm{M}_{1} \text { on the right and backward of the optical axis } \\
\phi_{2}=5 \pi / 4 & \mathrm{M}_{2} \text { on the right and forward of the optical axis } \\
\phi_{3}=3 \pi / 4 & \mathrm{M}_{3} \text { on the left and forward of the optical axis } \\
\phi_{4}=\pi / 4 & \mathrm{M}_{4} \text { on the left and backward of the optical axis }
\end{array}
$$

The scanning plane is normal to the spacecraft longitudinal axis, $R_{1}=R_{I}$ and the viewing vector is converted from $R_{2}$ to $R_{I}$ with the matrix $\mathbf{M}_{2}$ (defined in 3.6) where the scanning angle concerns the optical axis:

$$
\begin{aligned}
& \boldsymbol{s} \boldsymbol{m}_{\boldsymbol{i}_{\mathbf{R}}}=\mathbf{M}_{\mathbf{I}} \boldsymbol{s} \boldsymbol{m}_{\boldsymbol{i}_{\mathbf{R}}} \\
& \boldsymbol{s} \boldsymbol{m}_{\boldsymbol{i}_{\mathbf{R}}} \\
& \\
&=\left[\begin{array}{ccc}
\cos \left(\alpha_{\text {opt }}\right) & 0 & -\sin \left(\alpha_{o p t}\right) \\
0 & 1 & 0 \\
\sin \left(\alpha_{o p t}\right) & 0 & \cos \left(\alpha_{o p t}\right)
\end{array}\right]\left[\begin{array}{c}
1 \\
\zeta \cdot \cos \left(\phi_{i}\right) \\
\zeta \cdot \sin \left(\phi_{i}\right)
\end{array}\right]=\left[\begin{array}{c}
\cos \left(\alpha_{o p t}\right)-\zeta \cdot \sin \left(\phi_{i}\right) \cdot \sin \left(\alpha_{o p t}\right) \\
\zeta \cdot \cos \left(\phi_{i)}\right. \\
\sin \left(\alpha_{o p t}\right)+\zeta \cdot \sin \left(\phi_{i}\right) \cdot \cos \left(\alpha_{o p t}\right)
\end{array}\right]
\end{aligned}
$$

| :---: | :---: | :--- |

## 5. EARTH LOCATION OF THE VIEWED POINT

Earth location of the viewed pixel is the calculation of the IFOV center latitude and longitude or, which is equivalent, of its cartesian coordinates in the reference frame $\mathrm{R}_{\mathrm{G}}$.

The unit vector of viewing direction, $\boldsymbol{s m}$, is known in the reference frame $\mathrm{R}_{\mathrm{s}}$ through the equations presented in section 4. $s m$, is converted from $R_{S}$ to $R_{G}$ by:

$$
s m_{\mathbf{R}_{G}}=\mathbf{T}^{\mathrm{T}} \mathbf{A}^{\mathrm{T}} s m_{\mathrm{R}_{\mathrm{S}}}
$$

The vector $\boldsymbol{O S}$, Earth's gravity centre to satellite, is known in $\mathrm{R}_{\mathrm{G}}$. The vector $\boldsymbol{O M}$, Earth's gravity centre to viewed point, is given by:

$$
O M_{\mathbf{R}_{\mathbf{G}}}=O S_{\mathbf{R}_{\mathbf{G}}}+D \boldsymbol{s m}_{\mathbf{R}_{\mathbf{G}}}
$$

where $D$, distance between the satellite and the viewed point, is the only unknown.
The viewed point is in the Earth's ellipsoid, which gives a second order equation in $D$ :

$$
\begin{gathered}
\quad \frac{O M(1)_{R_{G}}^{2}}{R_{E}^{2}}+\frac{O M(2)_{R_{G}}^{2}}{R_{E}^{2}}+\frac{O M(3)_{R_{G}}^{2}}{R_{P}^{2}}=1 \\
\Leftrightarrow \quad a \cdot D^{2}+2 \cdot b \cdot D+c=0 \\
\text { with } \quad a=\operatorname{sm}(1)_{R_{G}}^{2}+\operatorname{sm}(2)_{R_{G}}^{2}+\operatorname{sm}(3)_{R_{G}}^{2} \cdot \frac{R_{E}^{2}}{R_{P}^{2}} \\
b=\operatorname{OS}(1)_{R_{G}} \cdot \operatorname{sm}(1)_{R_{G}}+O S(2)_{R_{G}} \cdot \operatorname{sm}(2)_{R_{G}}+O S(3)_{R_{G}} \cdot \operatorname{sm}(3)_{R_{G}} \cdot \frac{R_{E}^{2}}{R_{P}^{2}} \\
c=O S(1)_{R_{G}}^{2}+O S(2)_{R_{G}}^{2}+O S(3)_{R_{G}}^{2} \cdot \frac{R_{E}^{2}}{R_{P}^{2}}-R_{E}^{2}
\end{gathered}
$$

$R_{E}$ and $R_{P}$ are respectively the terrestrial equatorial and polar radius
$D$ is the smallest solution of the equation (the other solution corresponds to the point where the viewing direction goes out of the Earth). As the variable $b$ is negative, $D$ is given by:

$$
D=\frac{-b-\sqrt{b^{2}-a \cdot c}}{a}
$$

With $D$, the vector $\boldsymbol{O} M_{\mathbf{R}_{\mathbf{G}}}$ can be calculated and its cartesian coordinates are converted into latitude and longitude.

The calculations presented in this section are done in the subroutine earthpix

| NWP SAF | AAPP DOCUMENTATION <br> AAPP Navigation | Doc ID : NWPSAF-MF-UD- <br> Oos- Navigation.doc <br> Version: 1.3 <br> Date : October 2011 |
| :---: | :---: | :--- |

## 6. SATELLITE AND SUN VIEWING ANGLES

The object, satellite or sun, and the point M are known in $\mathrm{R}_{\mathrm{G}}$. The vector $\boldsymbol{M S}$, point to object, is calculated in $\mathrm{R}_{\mathrm{G}}$ then converted to $\mathrm{R}_{\mathrm{L}}$ with the conversion matrix $\mathbf{L}$ (defined in 3.2):

$$
\begin{aligned}
& M S_{\mathbf{R}_{\mathbf{G}}}=O S_{\mathbf{R}_{\mathbf{G}}}-O M_{\mathbf{R}_{\mathbf{G}}} \\
& M S_{\mathbf{R}_{\mathrm{L}}}=\mathbf{L} M S_{\mathbf{R}_{\mathbf{G}}}
\end{aligned}
$$

As indicated in 3.2, $M S_{\mathbf{R}_{\mathbf{L}}}$ is given by:

$$
\boldsymbol{M S}=D\left[\begin{array}{c}
\sin (\theta) \cdot \sin (\pi-A z) \\
\sin (\theta) \cdot \cos (\pi-A z) \\
\cos (\theta)
\end{array}\right]
$$

where $\theta$ is the zenith angle, $A z$ the azimuth angle and $D$ the distance point-to-object.

So, the zenith and azimuth angles are calculated by:

$$
\begin{aligned}
& \theta=\operatorname{arcos}\left(\frac{M S(3)_{R_{L}}}{M S}\right) \\
& A z=\pi-\operatorname{datan} 2\left(M S(2)_{R_{L}}, M S(1)_{R_{L}}\right)
\end{aligned}
$$

These calculations are done in the subroutine zenazi, for the general case, and by the subroutine trackang, for the case of a tracking station.

## 7. FOOTPRINT CALCULATION

### 7.1. PRINCIPLES

For a sounder having a rather large IFOV, it may be useful to locate not only the IFOV center but also the footprint, i.e. the surface on Earth corresponding to the IFOV. This section presents an exact calculation of the footprint. Such a method is probably over complicated for most applications but can be used as reference to test approximate formulas.

The IFOV is generally delimited by a cone. The cone axis is the viewing direction of the pixel center and its half angle, $\varepsilon$, is a small angle. $\varepsilon$ is equal to half of the IFOV width, which is the parameter commonly used to describe the instrument characteristics.

There is not a unique subroutine associated to each subsection of section 7:

## footprint

calculates a footprint in $\mathrm{R}_{\mathrm{I}}$, as presented in 7.1 and 7.2

## footprint_iasi

calculates the four IASI footprints in $\mathrm{R}_{\mathrm{I}}$, as presented in 7.3

## contour_sondeur_avhrr

calculates a footprint in geographical coordinates then in AVHRR coordinates (call footprint and other routines)
ellipse_sondeur_avhrr
calculates a footprint in AVHRR coordinates, according to the ellipse approximation presented in 7.2 (call footprint and other routines)
contour_iasi_avhrr
calculates the four IASI footprints in AVHRR coordinates (call footprint_iasi and other routines)

### 7.2. FOOTPRINT FOR A RADIOMETER SCANNING IN A PLANE

The viewing direction of the pixel center, which is the cone axis, is aligned with $X_{2}$ axis. Any viewing direction, $\boldsymbol{s p}$, lying in the cone is given in $\mathrm{R}_{2}$ by:

$$
\boldsymbol{s} \boldsymbol{p}_{R_{2}}=\left[\begin{array}{c}
1 \\
\varepsilon \cdot \cos (\psi) \\
\varepsilon \cdot \sin (\psi)
\end{array}\right] \quad \text { with } \psi \text { varying from } 0 \text { to } 2 \pi
$$

The viewing vector is converted from $R_{2}$ to $R_{1}$ with the matrix $\mathbf{M}_{2}$ :

$$
\boldsymbol{s} \boldsymbol{R}_{\mathbf{R}_{\mathbf{1}}}=\mathbf{M}_{\mathbf{2}} \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{2}}}=\left[\begin{array}{ccc}
\cos (\alpha) & 0 & -\sin (\alpha) \\
0 & 1 & 0 \\
\sin (\alpha) & 0 & \cos (\alpha)
\end{array}\right] \mathrm{x}\left[\begin{array}{c}
1 \\
\varepsilon \cdot \cos (\psi) \\
\varepsilon \cdot \sin (\psi)
\end{array}\right]
$$

$$
\boldsymbol{s} \boldsymbol{p}_{\mathrm{R}_{1}}=\left[\begin{array}{c}
\cos (\alpha)-\varepsilon \cdot \sin (\psi) \cdot \sin (\alpha) \\
\varepsilon \cdot \cos (\psi) \\
\sin (\alpha)+\varepsilon \cdot \sin (\psi) \cdot \cos (\alpha)
\end{array}\right] \quad 0 \leq \psi \leq 2 \pi
$$

For a cross-track scanner, $\beta=0$, the above formula directly gives viewing vector in $R_{I}$. In the general case, the viewing vector is converted from $R_{1}$ to $R_{I}$ with the matrix $\mathbf{M}_{1}$ defined in 3.6:

$$
\begin{aligned}
& \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{I}}}=\mathbf{M}_{\mathbf{1}} \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{1}}}=\left[\begin{array}{ccc}
\cos (\beta) & -\sin (\beta) & 0 \\
\sin (\beta) & \cos (\beta) & 0 \\
0 & 0 & 1
\end{array}\right] \mathrm{x}\left[\begin{array}{c}
\cos (\alpha)-\varepsilon \cdot \sin (\psi) \cdot \sin (\alpha) \\
\varepsilon \cdot \cos (\psi) \\
\sin (\alpha)+\varepsilon \cdot \sin (\psi) \cdot \cos (\alpha)
\end{array}\right] \\
& \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{I}}}=\left[\begin{array}{c}
\cos (\beta) \cdot[\cos (\alpha)-\varepsilon \cdot \sin (\psi) \cdot \sin (\alpha)]-\sin (\beta) \varepsilon \cdot \cos (\psi) \\
\sin (\beta) \cdot[\cos (\alpha)-\varepsilon \cdot \sin (\psi) \cdot \sin (\alpha)]+\cos (\beta) \varepsilon \cdot \cos (\psi) \\
\sin (\alpha)+\varepsilon \cdot \sin (\psi) \cdot \cos (\alpha)
\end{array}\right] \quad 0 \leq \psi \leq 2 \pi
\end{aligned}
$$

Earth location of any point on the IFOV border (i.e. the point corresponding to $\boldsymbol{s p}$ ) is the same as Earth location of the IFOV center and it follows equations of section 5 . If the objective is to obtain the footprint in AVHRR coordinates, the geographical coordinates are then converted into AVHRR line and pixel numbers.

An ellipse is a good approximation of the footprint. The semi-axis in line is the distance between the IFOV center, M, (already calculated in 4.2 ) and the point Q at $\psi=0$ :

$$
\left.\boldsymbol{s} \boldsymbol{q}_{\mathbf{R}_{\mathbf{I}}}=\left[\begin{array}{c}
\cos (\beta) \cdot \cos (\alpha)-\varepsilon \cdot \sin (\beta) \\
\sin (\beta) \cdot \cos (\alpha)+\varepsilon \cdot \cos (\beta) \\
\sin (\alpha)
\end{array}\right] \quad \boldsymbol{s \boldsymbol { m } _ { \mathbf { R } _ { \mathbf { I } } } = [ \begin{array} { c } 
{ \operatorname { c o s } ( \beta ) \cdot \operatorname { c o s } ( \alpha ) } \\
{ \operatorname { s i n } ( \beta ) \cdot \operatorname { c o s } ( \alpha ) } \\
{ \operatorname { s i n } ( \alpha ) }
\end{array} ] , ~ ]} \begin{array}{c}
\end{array}\right]
$$

The semi-axis in pixel is the distance between the IFOV center and the point Q at $\psi=\pi / 2$ : However, if the objective is to obtain the footprint in AVHRR coordinates, there is a very simple formula:

$$
a_{P I X}=\frac{\varepsilon}{\alpha_{\text {step }}(A H R R)} \quad \text { in number of AVHRR pixels }
$$

### 7.3. FOOTPRINT FOR CONICAL SCANNING

The pixel center viewing direction, which is the cone axis, is aligned with the $X_{3}$ axis. of the reference frame $R_{3}$ defined in 3.6. Any viewing direction, $\boldsymbol{s p}$, lying in the cone is given in $R_{3}$ by:

$$
\boldsymbol{s} \boldsymbol{p}_{R_{3}}=\left[\begin{array}{c}
1 \\
\varepsilon \cdot \cos (\psi) \\
\varepsilon \cdot \sin (\psi)
\end{array}\right] \quad 0 \leq \psi \leq 2 \pi
$$

The viewing vector is converted from $R_{3}$ to $R_{1}$ with the matrix $\mathbf{M}_{3}$ :

$$
s p_{\mathrm{R}_{1}}=\mathrm{M}_{3} s p_{\mathrm{R}_{3}}
$$

$$
\begin{aligned}
& \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{1}}=\left[\begin{array}{ccc}
\cos (\delta) & -\sin (\delta) & 0 \\
\sin (\delta) \cdot \cos (\phi) & \cos (\delta) \cdot \cos (\phi) & -\sin (\phi) \\
\sin (\delta) \cdot \sin (\phi) & \cos (\delta) \cdot \sin (\phi) & \cos (\phi)
\end{array}\right] \times\left[\begin{array}{c}
1 \\
\varepsilon \cdot \cos (\psi) \\
\varepsilon \cdot \sin (\psi)
\end{array}\right] \\
& \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{1}}=\left[\begin{array}{c}
\cos (\delta)-\boldsymbol{\varepsilon} \cdot \cos (\psi) \cdot \sin (\delta) \\
\sin (\delta) \cdot \cos (\phi)+\varepsilon \cdot[\cos (\psi) \cdot \cos (\phi) \cdot \cos (\delta)-\sin (\psi) \cdot \sin (\phi)] \\
\sin (\delta) \cdot \sin (\phi)+\varepsilon \cdot[\cos (\psi) \cdot \sin (\phi) \cdot \cos (\delta)+\sin (\psi) \cdot \cos (\phi)]
\end{array}\right] 0 \leq \psi \leq 2 \pi
\end{aligned}
$$

If the cone axis is aligned with the instrument vertical, $\beta=0$, the above formula directly gives viewing vector in $R_{I}$. In the general case, the viewing vector is converted from $R_{1}$ to $R_{I}$ with the matrix $\mathbf{M}_{1}$ defined in 3.6:

$$
\begin{array}{ll} 
& \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{I}}}=\mathbf{M}_{\mathbf{1}} \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{1}}}=\left[\begin{array}{ccc}
\cos (\beta) & -\sin (\beta) & 0 \\
\sin (\beta) & \cos (\beta) & 0 \\
0 & 0 & 1
\end{array}\right] \mathrm{x} \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{1}}} \\
\Leftrightarrow \quad & s p_{R_{t}}(1)=\cos (\beta) \cdot s p_{R_{1}}(1)-\sin (\beta) \cdot s p_{R_{1}}(2) \\
& s p_{R_{t}}(1)=\sin (\beta) \cdot s p_{R_{1}}(1)+\cos (\beta) \cdot s p_{R_{1}}(2) \\
& s p_{R_{t}}(3)=s p_{R_{1}}(3)
\end{array}
$$

### 7.4. IASI FOOTPRINT

The IFOV of each IASI pixel is delimited by a cone. The cone axis is the viewing direction of the pixel center and its half angle, $\varepsilon$, is a small angle.
The four IASI pixels lie in a cone whose axis is the optical axis, aligned with the axis $X_{2}$ of $R_{2}$. We now introduce a reference frame $R_{4 i}$, which is similar to the reference frame $R_{3}$ used for the conical scanning (defined in 3.6). $\mathrm{R}_{4 \mathrm{i}}$ has its X-axis, aligned with the viewing direction of one IASI pixel $\mathrm{M}_{\mathrm{i}}$ and is deduced from $\mathrm{R}_{2}$ by two rotations:

- rotation of an angle $\phi_{i}$ about axis $\mathrm{X}_{2}$, which gives an intermediate reference frame
- rotation of an angle $\zeta$ about the Z-axis of the intermediate reference frame.

The conversion matrix from $\mathrm{R}_{4 \mathrm{i}}$ to $\mathrm{R}_{2}, \mathbf{M}_{4 \mathrm{i}}$, is similar to the matrix $\mathbf{M}_{\mathbf{3}}$ (defined in 3.6), where the angles $\delta$ and $\phi$ are replaced respectively by $\zeta$ and $\phi_{I}$ and $\zeta$ is a small angle:

$$
\mathbf{M}_{\mathbf{4 i}}=\left[\begin{array}{ccc}
1 & -\zeta & 0 \\
\zeta \cdot \cos \left(\phi_{i}\right) & \cos \left(\phi_{i}\right) & -\sin \left(\phi_{i}\right) \\
\zeta \cdot \sin \left(\phi_{i}\right) & \sin \left(\phi_{i}\right) & \cos \left(\phi_{i}\right)
\end{array}\right]
$$

Any viewing direction, $\boldsymbol{s p}$, lying in the cone that corresponds to the footprint of the IASI pixel $\mathrm{M}_{\mathrm{i}}$, is given in $\mathrm{R}_{4 \mathrm{i}}$ by:

$$
\boldsymbol{s} \boldsymbol{p}_{4 i}=\left[\begin{array}{c}
1 \\
\varepsilon \cdot \cos (\psi) \\
\varepsilon \cdot \sin (\psi)
\end{array}\right] \quad 0 \leq \psi \leq 2 \pi
$$

AAPP DOCUMENTATION
Doc ID : NWPSAF-MF-UD-
005_Navigation.doc
Version: 1.3
Date : October 2011

The viewing vector is converted from $R_{4}$ to $R_{2}$ with the matrix $\mathbf{M}_{4 i}$ :

$$
\boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{2}}}=\mathbf{M}_{\mathbf{4 i}} \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{4 i}}}=\left[\begin{array}{ccc}
1 & -\zeta & 0 \\
\zeta \cdot \cos \left(\phi_{i}\right) & \cos \left(\phi_{i}\right) & -\sin \left(\phi_{i}\right) \\
\zeta \cdot \sin \left(\phi_{i}\right) & \sin \left(\phi_{i}\right) & \cos \left(\phi_{i}\right)
\end{array}\right] \times\left[\begin{array}{c}
1 \\
\varepsilon \cdot \cos (\psi) \\
\varepsilon \cdot \sin (\psi)
\end{array}\right]
$$

As $\varepsilon$ and $\zeta$ are both small angles, only the first order terms in $\varepsilon$ or $\zeta$ are kept:

$$
\boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{2}}=\left[\begin{array}{c}
1 \\
\zeta \cdot \cos \left(\phi_{i}\right)+\varepsilon \cdot\left[\cos (\psi) \cdot \cos \left(\phi_{i}\right)-\sin (\psi) \cdot \sin \left(\phi_{i}\right)\right] \\
\zeta \cdot \sin \left(\phi_{i}\right)+\varepsilon \cdot\left[\cos (\psi) \cdot \sin \left(\phi_{i}\right)+\sin (\psi) \cdot \cos \left(\phi_{i}\right)\right]
\end{array}\right]=\left[\begin{array}{c}
1 \\
\zeta \cdot \cos \left(\phi_{i}\right)+\varepsilon \cdot \cos \left(\phi_{i}+\psi\right) \\
\zeta \cdot \sin \left(\phi_{i}\right)+\varepsilon \cdot \sin \left(\phi_{i}+\psi\right)
\end{array}\right]
$$

Then it is converted from $R_{2}$ then to $R_{I}$ with the matrix $\mathbf{M}_{2}$ :

$$
\begin{aligned}
& \boldsymbol{s} \boldsymbol{R}_{\mathbf{R}_{\mathbf{I}}}=\mathbf{M}_{\mathbf{2}} \boldsymbol{s} \boldsymbol{p}_{\mathbf{R}_{\mathbf{2}}}=\left[\begin{array}{ccc}
\cos \left(\alpha_{o p t}\right) & 0 & -\sin \left(\alpha_{o p t}\right) \\
0 & 1 & 0 \\
\sin \left(\alpha_{o p t}\right) & 0 & \cos \left(\alpha_{o p t}\right)
\end{array}\right] \mathrm{x}\left[\begin{array}{c}
1 \\
\zeta \cdot \cos \left(\phi_{i}\right)+\varepsilon \cdot \cos \left(\phi_{i}+\psi\right) \\
\zeta \cdot \sin \left(\phi_{i}\right)+\varepsilon \cdot \sin \left(\phi_{i}+\psi\right)
\end{array}\right] \\
& \boldsymbol{p}_{\mathbf{R}_{\mathbf{I}}}=\left[\begin{array}{c}
\cos \left(\alpha_{o p t}\right)-\sin \left(\alpha_{o p t}\right) \cdot\left[\zeta \cdot \sin \left(\phi_{i}\right)+\varepsilon \cdot \sin \left(\phi_{i}+\psi\right)\right] \\
\zeta \cdot \cos \left(\phi_{i}\right)+\varepsilon \cdot \cos \left(\phi_{i}+\psi\right) \\
\sin \left(\alpha_{o p t}\right)+\cos \left(\alpha_{o p t}\right) \cdot\left[\zeta \cdot \sin \left(\phi_{i}\right)+\varepsilon \cdot \sin \left(\phi_{i}+\psi\right)\right]
\end{array}\right]
\end{aligned}
$$

## 8. ORBIT PREDICTION USING 2-LINE ELEMENTS

### 8.1. RESULTS OF A 6-MONTH COMPARISON

At the Centre de Meteorologie Spatiale (CMS) of Meteo-France, three modes of AAPP navigation have been run under operational conditions, using respectively:

- TBUS bulletins, which is the standard option of AAPP version 1 to 4,
- Two-Line element sets, which is the new option proposed in AAPP-5,
- ARGOS bulletins, which is the CMS operational mode.

Here are presented the results obtained over a 6-month period for NOAA-16 and NOAA-17.

The consistency of each orbital element data set is given by the orbit extrapolation error, which is the distance between the position predicted with the current bulletin and the position of the next bulletin, divided by the time interval between these two bulletins. Statistics of this parameter are presented in Table 8-1 and examples of its temporal variation are shown in the upper plot of Figure 8-1 and Figure 8-2.

| Satellite | Method | bias | sigma | r.m.s |
| :--- | :--- | :--- | :--- | :--- |
| noaa16 | tbus | -2.92 | 1.25 | 3.17 |
|  | 2line | -0.05 | 0.76 | 0.77 |
|  | argos | 0.61 | 0.80 | 1.01 |
| noaa17 | tbus | 4.70 | 1.95 | 5.09 |
|  | 2line | -0.06 | 0.66 | 0.67 |
|  | argos | 0.78 | 1.00 | 1.27 |

Table 8-1 : extrapolation error in $\mathbf{k m}$ per day, from 2003/09/22 to 2004/03/15

The results obtained with the Two-Line element sets are obviously better than those obtained with the TBUS bulletins, for both satellites.

The CMS operational suite for AVHRR imagery includes an Automatic Navigation Adjustment (ANA), which is a correlation technique based on coastal landmarks. This allows calculation, for each landmark successfully processed by ANA, of the navigation error as the distance between the AAPP calculated position and the ANA "measured" position. The AAPP position is calculated with a "default" attitude error, which is a parameter introduced by the user (in the satid file) and usually derived from ANA attitude earlier results. The default attitude values used in the 6 -month experiment are given in Table 8-2. The default attitude error is calculated separately for the three types of orbital elements, since the so-called "pitch bias" corresponds actually to a pitch error and to an orbit extrapolation error.

| Satellite | Method | yaw | roll | pitch |
| :--- | :--- | :--- | :--- | :--- |
| noaa16 | tbus | 0.2 | 0.7 | -0.6 |
|  | 2line | 0.2 | 0.7 | 0.6 |
|  | argos | 0.2 | 0.7 | 0.7 |
| noaa17 | tbus | 0.8 | 0.2 | 4.7 |
|  | 2line | 0.8 | 0.2 | 0.9 |
|  | argos | 0.8 | 0.2 | 1.9 |

Table 8-2 : NOAA-16 and NOOA-17 defaut attitude values (in mrad)

| NWP SAF | AAPP DOCUMENTATION <br> AAPP Navigation | Doc ID : NWPSAF-MF-UD005_Navigation.doc Version : 1.3 <br> Date : October 2011 |
| :---: | :---: | :---: |

Statistics of the AVHRR navigation error have been calculated over all landmarks of a pass, then over all passes of the 6 -month period and the final results are presented in table 3. Examples of the navigation error temporal variation are shown in the plot entitled "distance rms error (km)" of Figure 8-1 and Figure 8-2.

| Satellite | Method | bias | sigma | r.m.s |
| :--- | :--- | :--- | :--- | :--- |
| noaa16 | tbus | 2.39 | 1.29 | 2.71 |
|  | 2line | 2.24 | 0.96 | 2.44 |
|  | argos | 2.04 | 0.82 | 2.20 |
| noaa17 | tbus | 3.12 | 2.27 | 3.86 |
|  | 2line | 2.09 | 0.84 | 2.25 |
|  | argos | 1.86 | 0.86 | 2.04 |

Table 8-3 : AVHRR navigation error in km , from 2003/09/22 to 2004/03/15, using AAPP default attitude. The statistics are derived from only the passes for which the yaw, roll and pitch have been estimated.

The navigation accuracy with the Two-Line element sets is better than the one with the TBUS bulletins. For NOAA-16, there is only a slight difference, probably because the default pitch error has partly compensated the orbit extrapolation error of the TBUS. For NOAA-17, there is a significant difference.

### 8.2. CONCLUSION

A new feature, orbit calculation using the Two-Line element sets, has been added to AAPP navigation. The AVHRR imagery is navigated more accurately with these data than with TBUS bulletin. The AAPP user can easily switch from TBUS to Two-Line data and it is recommended to do so.
